Definitions.

- Given a matching M in a graph G, a vertex that is not incident to any edge of M is called a free vertex w.r..t. M.
- For a matching M a path P in G is called an alternating path if edges in M alternate with edges not in M.
- An alternating path is called an augmenting path for matching M if it ends at distinct free vertices.

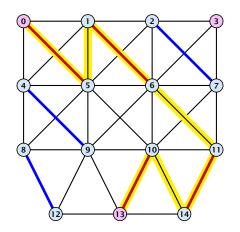

Theorem 1

A matching M is a maximum matching if and only if there is no augmenting path w. r. t. M.

Augmenting Paths in Action

Augmenting Paths in Action

Proof.

- \Rightarrow If M is maximum there is no augmenting path P, because we could switch matching and non-matching edges along P. This gives matching $M' = M \oplus P$ with larger cardinality.
- \Leftarrow Suppose there is a matching M' with larger cardinality. Consider the graph H with edge-set $M' \oplus M$ (i.e., only edges that are in either M or M' but not in both).

Each vertex can be incident to at most two edges (one from M and one from M'). Hence, the connected components are alternating cycles or alternating path.

As |M'| > |M| there is one connected component that is a path P for which both endpoints are incident to edges from M'. P is an alternating path.

Algorithmic idea:

As long as you find an augmenting path augment your matching using this path. When you arrive at a matching for which no augmenting path exists you have a maximum matching.

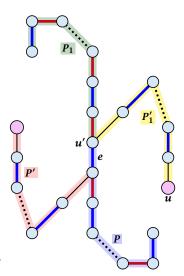

Theorem 2

Let G be a graph, M a matching in G, and let u be a free vertex $w.r.t.\ M$. Further let P denote an augmenting path $w.r.t.\ M$ and let $M' = M \oplus P$ denote the matching resulting from augmenting M with P. If there was no augmenting path starting at u in M then there is no augmenting path starting at u in M'.

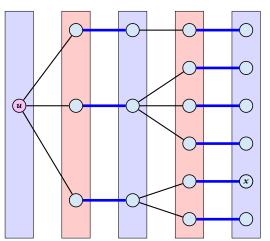

The above theorem allows for an easier implementation of an augmenting path algorithm. Once we checked for augmenting paths starting from u we don't have to check for such paths in future rounds.

Proof

- Assume there is an augmenting path P' w.r.t. M' starting at u.
- If P' and P are node-disjoint, P' is also augmenting path w.r.t. M (∮).
- ▶ Let u' be the first node on P' that is in P, and let e be the matching edge from M' incident to u'.
- u' splits P into two parts one of which does not contain e. Call this part P₁. Denote the sub-path of P' from u to u' with P'₁.
- $P_1 \circ P_1'$ is augmenting path in M (3).

Construct an alternating tree.

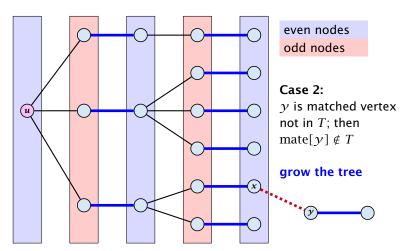

even nodes odd nodes

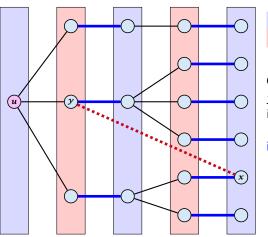

Case 1: y is free vertex not contained in T

you found alternating path

Construct an alternating tree.

Construct an alternating tree.

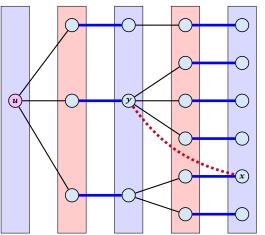

even nodes odd nodes

Case 3:y is already contained in T as an odd vertex

ignore successor y

Construct an alternating tree.

even nodes odd nodes

Case 4:

y is already contained in T as an even vertex

can't ignore y

does not happen in bipartite graphs

```
Algorithm 25 BiMatch(G, match)
 1: for x \in V do mate[x] \leftarrow 0:
